Competence in ceramics
Gebr. Pfeiffer looks back on a long and successful history that is based on high-quality products, closeness to the customer and an international standing. Even in an environment undergoing fast changes we remain loyal to these standards. That is why our company and its employees will shape the future.

Since our foundation in 1864 we have always participated in the development of modern process technology for grinding, separating, drying, hydrating and calcining.

With more than 450 employees, our center of competence in Kaiserslautern as well as our subsidiaries in the United States and India are active all over the world, supported by an extensive network of cooperations and representations.

Our success is the result of a wide product range, a modern test station, in-house workshops with a high vertical capacity and an extensive store of experience especially with the cement, lime, gypsum and ceramics industries.

We regard the finding of customized systems that meet your special requirements as our most important task.

We ensure a long service life for our plants and machines by establishing long-lasting cooperations in a spirit of partnership to the benefit of a high-quality finished product, safe plant operation, economic viability and technical progress.
For thousands of years mankind has been accompanied by ceramics. It is essential not only to everyday life but also to the building trade.

Over the last century application in engineering has become ever more significant. Today the ceramics industry covers the most diverse product ranges, e.g. bricks and tiles, roofing tiles, ducts, tableware and sanitary ware, refractories and technical ceramics, all made from natural raw materials such as clay, kaolin, quartz and feldspar.

For this reason raw material processing ranks high in ceramics industry. Homogeneity and fineness as well as the elimination or fine-grinding of impurities, to render them harmless, influence both the further production process and the quality of the burnt finished product. Increasing quality requirements and cost pressure demand effective processes. Here, dry processing as a continuous and automated process points the way forward.

We design and manufacture for you complete processing plants or offer you from our extensive manufacturing program individual machines for the solution of your special problem.

Pfeiffer has set standards in the dry processing of ceramic raw materials. The ceramics industry has confidence in us.

We are competent in

- grinding
- drying
- separating

The PFEIFFER product range comprises:

- the PFEIFFER MPS vertical roller mill ...........................................9 ideal for the combined grinding and drying
- the PFEIFFER MRD/MRE ball mill .............................................10 ideal for the fine-grinding of highly abrasive raw materials
- the PFEIFFER distribution table air separator .........................11 type SUT with constant speed type SUV with variable speed
- the PFEIFFER high-efficiency classifier ...................................11 type SLV with variable speed
- the PFEIFFER TRT Triplex dryer .............................................13 the space-saving dryer for ceramic raw materials of all usual grain sizes
Our machines and processes for the ceramics industry

1 Drying
In PFEIFFER Triplex dryers, lumpy ceramic raw materials such as clay, kaolin, feldspar or quartz are dried to the required residual moisture.

The materials obtained this way can be processed further either in grinding plants or in separating plants. Also they can be directly forwarded to the plastic shaping.

2 Combined grinding and drying
In PFEIFFER MPS vertical roller mills, lumpy ceramic materials with a low to medium abrasiveness are ground, separated and dried. The finished product fineness can be set within wide limits from 0.02 to 0.5 mm. If required, any foreign material contained in the feed material can be separated and removed from the system during the process. With feed moistures exceeding 12 % the material is pre-dried in a Triplex dryer for economical reasons.

With coarse and fine ceramics the ground, pulverized materials are used as basic materials for the manufacture of ceramic working masses and mixtures. During grinding the raw materials, which themselves are not entirely homogenous and have mostly for geological reasons different chemical and physical properties, are homogenized.

3 Grinding of hard materials
Lumpy and hard ceramic feed materials with a high abrasiveness such as quartz, feldspar, sinter magnesite, bauxite or fireclay, are fine-processed in circuit with ball mills and separators or coarse-processed in several separating stages. The fineness of the finished products can be set within wide limits from 0.01 to 0.5 mm. With feed moistures exceeding 2 % here, too, the material is pre-dried in a Triplex dryer.

The ground finished products are used in all fields of the ceramics industry. During grinding the raw materials which themselves are not entirely homogenous and have mostly for geological reasons different chemical and physical properties, are homogenized.

The grits fall back into the center of the grinding zone. The finished product leaves the classifier together with the gas stream and is separated in downstream cyclones or a filter unit.

The advantages
Low investment costs
MPS mills require few ancillary machines, no or little walled-in space, they operate dust-free and have a low noise level.

Low electric power consumption
The grinding principle and the high-efficiency classifier reduce the electric power consumption by up to 40 % compared with conventional ball mills.

Optimum utilization of process heat
MPS vertical roller mills allow an optimum utilization of the thermal energy of low-temperature process gases.

Maximum availability
Low specific wear rates, high-quality wear materials and progressive repair concepts reduce downtimes of MPS vertical roller mills to a minimum.

Favorable control behavior
High drying capacity, short retention times, and remote control of the grinding pressure and the speed of the separating wheel allow MPS vertical roller mills to be operated fully automatically even with fluctuating raw material qualities.

The working principle
Three stationary grinding rollers roll on a slowly rotating grinding table. The material is drawn in between grinding rollers and grinding track and ground by pressure and shear. The compression force required for the comminution of the material is generated by a hydropneumatic tensioning system.

The material is ground and conveyed by centrifugal force towards the stationary nozzle ring. Gases (air or hot gases) flowing up through the nozzle ring mix with the material and carry it up to the classifier. In the separating zone a rotating separating wheel separates the ground and dried material into fine finished product and grits.
The PFEIFFER ball mills

The solution to your problem
Grinding of highly-abrasive hard materials
throughput rate 1 - 50 t/h
target fineness degree 0.01 - 5 mm
feed size 2 - 30 mm

The working principle
The material is fed into the ball mill through the neck bearing journal. Grinding balls grind it by impact and friction.

The ground material leaves the mill either through discharge slots arranged around the mill tube, through a discharge diaphragm or according to the overflow principle through the neck bearing journal at the end of the mill tube.

Design and setting of discharge slots and discharge diaphragm define the grain size distribution of the ground material.

With circuit operation the target fineness can be set at the separator or, in case of coarse grinding with a downstream screening machine, by selecting a certain mesh width.

Ball mill types
MRD  ball mill with center discharge
MRE  ball mill with end discharge
MKS  screen ball mill
MKF  ball mill with grinding beam

Fine-grinding is generally effected in mills of the MRD and MRE series, whereas coarse grinding is effected in mills of the MKS and MKF series.

If required metal attrition due to wear in the grinding and separating zone can largely be avoided with a ceramic lining applied to mill and separator and with grinding bodies made of Al₂O₃ or flintstone. The separators can also be lined with polyurethane.

The advantages
Low electric power consumption
Fine material particles cannot be ground too finely due to a short grinding track and an adjustable retention time.

Adjustable grain size distribution
With gravity discharge mills, product fineness and grain size distribution are adjustable by a variation of the discharge slots.

Maximum availability
Plain, robust design, wear-resistant lining, low maintenance.
The PFEIFFER separators

The solution to your problem
Separators for circuit operation with mills and for grain sizing in the fine particle range

The distribution table air separator type SUT with constant speed
The cost-effective separator for the production of primarily one target fineness degree,
typical target fineness degree 90 - 200 μm.

The distribution table air separator type SUV with variable speed
Your solution when it comes to the production of several target fineness degrees.

The high-efficiency separator type SLV with variable speed
For ultra-sharp separation and the production of high fineness degrees

The working principle
An air stream transports the material into the separating zone where it is separated into a fine product and a coarse product. The coarse product is always discharged through a cone, for example for further processing.

With the SUT and SUV series the fine product is discharged through an integrated cone, with the SLV series it is separated in a downstream cyclone or filter.

The advantages
Sharp separation
Uniform product distribution in the separating zone due to a central material infeed; pre-separation and post-separation as a result of an optimum arrangement of the louvre.

Many and diverse applications
All separators can be used for separation in one passage or in circuit operation with a mill.

No need for dust collection equipment
All distribution table air separators can be operated without dust collection equipment.

Long service life
Special linings protect our separators from wear. We can offer partial or complete linings made of steel, rubber, synthetic or ceramic materials, depending on the type and abrasiveness of the processed material.

The PFEIFFER Triplex dryer

The solution to your problem
Drying or pre-drying of ceramic raw materials
finished product rate  1 - 200 t/h
feed size      150 mm max
feed moisture   all usual feed moistures
residual moisture  0.1 % max

The working principle
The Triplex dryer type TRT operates on the uniflow principle, i.e. material and hot gases flow in the same direction and pass through the concentric dryer tubes from the center outwards.

The material to be dried is fed into the innermost tube, it passes through the dryer and is discharged through double pendulum flaps fitted to the dust jacket.

The residual moisture of the dried material is controlled by a regulation of exhaust gas temperature and retention time of the material in the dryer.

The advantages
The hot gas is produced in a combustion chamber. Solid, fluid or gaseous fuels can be used for combustion. A utilization of process gases is possible as well.

The dryer exhaust gases are dedusted in a filter.

Low space requirement
As a consequence of the short design and the concentric arrangement of the dryer tubes the investment cost for buildings and foundations is low.

Short dryer start-up and shut-down times
No ceramic lining is required, the dryer is made of temperature-resistant steel plates.

Careful material treatment
The material is treated with care, because of the uniflow principle it will not overheat.

Low thermal energy consumption
The small dryer surface and the uniflow principle result in a very low heat loss by radiation.
PFEIFFER machines and industrial plants
**Test station**

In our test station raw materials are tested for their processing qualities, and in our laboratories these raw materials are characterized by taking all the relevant norms/specifications and standards into account.

For these tests pilot plants with machines from our manufacturing program are available for throughput rates from 0.5 to 10 t/h. The results of the tests serve as a basis for the selection of the suitable process for a given application and for the machine and process dimensioning.

**Spare parts service**

Original spare parts guarantee that your plant will operate economically even many years after its erection. Take advice from our experienced engineers. Our electronic wear analysis for the grinding elements of the MPS mill records the actual wear progress and allows a selective spare parts inventory and maintenance.

**Erection and commissioning**

Experienced engineers and supervisors are available for erection and commissioning and for the training of your operating and maintenance personnel.

**Consultation**

We are competent in designing and planning not only new plants but also plant conversions, the upgrading and modernization of existing plants, maintenance and repair, the selection of suitable wear materials and in answering all process related questions.

**Manufacture**

We have our own mechanical workshops and foundry. All phases of our product manufacture are carefully planned. The quality of our products is systematically supervised and documented pursuant to the quality management system of DIN ISO 9001.
N.B.: Some details of the figures may differ from the newest design.
